Explanation of the Maple Code for the Key Vanishing Lemma II

For a Second Main Theorem about 3 Generic Conics

March 27, 2026

0. Introduction

This Maple code is an integral part of the verification of the Key Vanishing Lemma II in the paper *A Second Main Theorem for Entire Curves Intersecting Three Conics* by Lei Hou, Dinh Tuan Huynh, Joël Merker, and Song-Yan Xie (arXiv:2512.03948). The lemma asserts that for a generic configuration of three conics $\mathcal{C} \subset \mathbb{P}^2$, the cohomology group

$$H^0\big(\mathbb{P}^2,\ E_{2,m}T^*_{\mathbb{P}^2}(\log \mathcal{C}) \otimes \mathcal{O}_{\mathbb{P}^2}(-t)\big) = 0$$

for all pairs (m, t) listed in Lemma II. This vanishing is essential for achieving the optimal constant $c = 5$ in the Second Main Theorem.

The proof follows the algebraic reduction described in Section 7 of the paper: a general invariant logarithmic 2-jet differential is expressed in terms of the logarithmic 1-forms $(\log A/C)'$ and $(\log B/C)'$ and their Wronskian, with coefficients that are rational functions whose denominators are powers of the Jacobian J. By expanding in two affine charts and imposing regularity (i.e., cancellation of all denominators), the problem reduces to a finite linear system over the integers. To make the computation tractable, a specific Fermat-type triple of conics is chosen, and the system is solved modulo a small prime $p = 5$. The only solution is the trivial one, proving the vanishing for that configuration, and by semi-continuity the same holds for generic conics.

The code is written in Maple and is organized into logical segments, each accompanied by a brief explanation. All listings together form the complete program used to obtain the numerical results reported in the paper.

1. Initialisation and Parameters

The weighted degree m and the twist t (here $t = -m + 4$) are set. The prime modulus is 5. The degrees of the homogeneous coefficient polynomials R, S, U, V, W are computed according to the formulas derived in Section 7.3.

```
restart: with(LinearAlgebra): with(Groebner):

m := 13;
twist := - m + 4;
p := 5;

dR := 3*(m-0) + twist:
dS := 3*(m-2) + twist:
dU := 3*(m-4) + twist:
dV := 3*(m-6) + twist:
dW := 3*(m-8) + twist:
```

Explanation: The parameters are chosen for the most demanding case $(m, t) = (13, 9)$. The degrees $dR, \ldots, dW$ ensure that the rational expression for the jet differential has homogeneous degree t after multiplying by the appropriate powers of the Jacobian.

2. Defining the Three Fermat-Type Conics

The three conics are given by explicit homogeneous quadratic polynomials in coordinates T, X, Y.

```
AA := 2*T^2 + 1*x^2 + 1*y^2;
BB := 1*T^2 + 2*x^2 + 1*y^2;
CC := 1*T^2 + 1*x^2 + 2*y^2;
```

Explanation: This choice makes the Jacobian J a product of the coordinate lines, which greatly simplifies the divisibility conditions.

3. Partial Derivatives and the Jacobian Matrix

All first and second order partial derivatives are computed, and the 3×3 Jacobian matrix is formed. Its determinant DD (up to a factor) is the local expression of the Jacobian J.

```
AT := diff(AA,T): BT := diff(BB,T): CT := diff(CC,T):
AX := diff(AA,X): BX := diff(BB,X): CX := diff(CC,X):
AY := diff(AA,Y): BY := diff(BB,Y): CY := diff(CC,Y):

ATT := diff(AA,T,T): ATX := diff(AA,T,X): ATY := diff(AA,T,Y):
AXX := diff(AA,X,X): AXY := diff(AA,X,Y): AYY := diff(AA,Y,Y):
BTT := diff(BB,T,T): BTX := diff(BB,T,X): BTY := diff(BB,T,Y):
BXX := diff(BB,X,X): BXY := diff(BB,X,Y): BYY := diff(BB,Y,Y):
CTT := diff(CC,T,T): CTX := diff(CC,T,X): CTY := diff(CC,T,Y):
CXX := diff(CC,X,X): CXY := diff(CC,X,Y): CYY := diff(CC,Y,Y):

MatDD := Matrix([[AT,BT,CT],
    [AX,BX,CX],
    [AY,BY,CY]]):
DD := factor(Determinant(MatDD));
```

Explanation: The derivatives are needed for the transformation between standard and logarithmic jets. The determinant DD will appear in denominators and must be cancelled by the numerator polynomials.

4. Logarithmic 1-Jets and 2-Jets

The logarithmic derivatives $(\log A/C)'$, $(\log B/C)'$ and their second derivatives are expressed using the chain rule.

```
Ap := AT*T1 + AX*X1 + AY*Y1:
Bp := BT*T1 + BX*X1 + BY*Y1:
Cp := CT*T1 + CX*X1 + CY*Y1:

App := + AT*T2 + AX*X2 + AY*Y2
    + ATT*T1*T1 + 2*ATX*T1*X1 + 2*ATY*T1*Y1 + AXX*X1*X1 + 2*AXY*X1*Y1 + AYY*Y1*
        Y1:

Bpp := + BT*T2 + BX*X2 + BY*Y2
    + BTT*T1*T1 + 2*BTX*T1*X1 + 2*BTY*T1*Y1 + BXX*X1*X1 + 2*BXY*X1*Y1 + BYY*Y1*
        Y1:

Cpp := + CT*T2 + CX*X2 + CY*Y2
    + CTT*T1*T1 + 2*CTX*T1*X1 + 2*CTY*T1*Y1 + CXX*X1*X1 + 2*CXY*X1*Y1 + CYY*Y1*
        Y1:

logACp := Ap/AA - Cp/CC:
logBCp := Bp/BB - Cp/CC:
```

```
logACpp := App/AA - Ap^2/AA^2 - (Cpp/CC - Cp^2/CC^2):
logBCpp := Bpp/BB - Bp^2/BB^2 - (Cpp/CC - Cp^2/CC^2):
```

Explanation: The formulas follow from the definition of logarithmic differentials. The quadratic terms appear because of the second derivative of the logarithm.

5. Affine Chart $\{T = 1\}$ (Coordinates x, y)

We set $T = 1$, $T1 = 0$, $T2 = 0$ and keep $x = X$, $y = Y$, $x1 = X1$, $y1 = Y1$, $x2 = X2$, $y2 = Y2$.

```
Carte_xy := {T = 1, X = x, Y = y,
    T1 = 0, X1 = x1, Y1 = y1,
    T2 = 0, X2 = x2, Y2 = y2}:

xyAA := subs(Carte_xy, AA):
xyBB := subs(Carte_xy, BB):
xyCC := subs(Carte_xy, CC):
xyDD := subs(Carte_xy, DD):

xylogACp := subs(Carte_xy, logACp):
xylogBCp := subs(Carte_xy, logBCp):

xylogACpp := subs(Carte_xy, logACpp):
xylogBCpp := subs(Carte_xy, logBCpp):
```

Explanation: This chart covers the part of $\mathbb{P}^2$ where $Z_0 \neq 0$. The expressions are simplified to polynomials in the affine coordinates.

6. Affine Chart $\{Y = 1\}$ (Coordinates t, x)

Similarly, we use $Y = 1$, $Y1 = 0$, $Y2 = 0$ and $t = T$, $x = X$, $t1 = T1$, $x1 = X1$, $t2 = T2$, $x2 = X2$.

```
Carte_tx := {T = t, X = x, Y = 1,
    T1 = t1, X1 = x1, Y1 = 0,
    T2 = t2, X2 = x2, Y2 = 0}:

txAA := subs(Carte_tx, AA):
txBB := subs(Carte_tx, BB):
txCC := subs(Carte_tx, CC):
txDD := subs(Carte_tx, DD):

txlogACp := subs(Carte_tx, logACp):
txlogBCp := subs(Carte_tx, logBCp):

txlogACpp := subs(Carte_tx, logACpp):
txlogBCpp := subs(Carte_tx, logBCpp):
```

Explanation: This second chart covers the remaining part of the projective plane and is necessary for the global regularity condition.

7. General Form of the Invariant Logarithmic 2-Jet Differential

According to Equation (final formula J) in the paper, any such jet differential is a sum of terms involving powers of the logarithmic Wronskian, with coefficients that are rational functions in A, B, C and powers of J. The following code constructs this expression symbolically.

```
Jet_ABC := + (1/(T*X*Y)^(m-0))
    * add(R[m-0-j,j] * logACp^(m-0-j) * logBCp^j *
      (logACp*logBCpp-logACpp*logBCp)^0, j=0..m-0)
    + (1/(T*X*Y)^(m-2))
    * add(S[m-3-j,j] * logACp^(m-3-j) * logBCp^j *
      (logACp*logBCpp-logACpp*logBCp)^1, j=0..m-3)
    + (1/(T*X*Y)^(m-4))
    * add(U[m-6-j,j] * logACp^(m-6-j) * logBCp^j *
      (logACp*logBCpp-logACpp*logBCp)^2, j=0..m-6)
    + (1/(T*X*Y)^(m-6))
    * add(V[m-9-j,j] * logACp^(m-9-j) * logBCp^j *
      (logACp*logBCpp-logACpp*logBCp)^3, j=0..m-9)
    + (1/(T*X*Y)^(m-8))
    * add(W[m-12-j,j] * logACp^(m-12-j) * logBCp^j *
      (logACp*logBCpp-logACpp*logBCp)^4, j=0..m-12):
```

Explanation: $R_{i,j}, S_{i,j}, U_{i,j}, V_{i,j}, W_{i,j}$ are placeholder homogeneous polynomials whose degrees are $dR, dS, \ldots$. The factor $(TXY)^{-(\text{power})}$ accounts for the Jacobian denominators.

8. Substitution in the Two Charts and Elimination of Second-Order Jets

In each chart we substitute the explicit expressions for the logarithmic jets and then eliminate the second-order variables x_2, y_2 (or t_2, x_2) using the relation that the standard Wronskian W''' is a linear combination of the logarithmic Wronskian and cubic terms. The variable `xyW` (or `txW`) represents the standard Wronskian.

```
xyJet_ABC := factor((x*y*xyAA*xyBB*xyCC)^m * (subs(y2=(xyW+x2*y1)/x1, xyJet_ABC
    ))):

xyJet := mtaylor(xyJet_ABC, [x1,y1,xyW], 100):

txJet_ABC := factor((t*x*txAA*txBB*txCC)^m * (subs(x2=(txW+t2*x1)/t1, txJet_ABC
    ))):

txJet := mtaylor(txJet_ABC, [t1,x1,txW], 100):
```

Explanation: The factor $(xyABC)^m$ cancels the denominators coming from A, B, C. The substitution replaces y_2 (or x_2) by an expression involving the Wronskian and the first-order jets, thereby reducing the jet differential to a polynomial in x_1, y_1, xyW (or t_1, x_1, txW).

9. Extracting Coefficients

We extract the coefficient of each monomial $x_1^i y_1^j (xyW)^k$ (and analogously for the t, x chart). These coefficients must vanish for the jet differential to be regular.

```
for k from 0 to m/3 do
    for j from 0 to m-3*k do
        xyEEEq[m-j-3*k,j,k] := factor(coeftayl(xyJet, [x1,y1,xyW]={0,0,0}, [m-j
            -3*k,j,k])):
    od:
od:

for k from 0 to m/3 do
    for j from 0 to m-3*k do
        txEEEq[m-j-3*k,j,k] := factor(coeftayl(txJet, [t1,x1,txW]={0,0,0}, [m-j
            -3*k,j,k])):
    od:
```

```
od:
```

Explanation: `coeftayl` extracts the coefficient of the specified monomial. The indices (i, j, k) satisfy $i + j + 3k = m$ because the weighted degree of the Wronskian is 3.

10. Imposing Divisibility by x and y (or t and x)

After extracting, the coefficients are polynomials in x, y (or t, x). For the section to be holomorphic across the divisors $\{x = 0\}$ and $\{y = 0\}$ (and $\{t = 0\}$, $\{x = 0\}$), the numerators must be divisible by the appropriate powers of these variables. The following custom procedures enforce this.

```
NFxy := proc(P,j,i)
    expand(mtaylor(P,x,j) + mtaylor(P,y,i) - mtaylor(mtaylor(P,y,i), x,j)):
end proc:

NFtx := proc(P,j,i)
    expand(mtaylor(P,t,j) + mtaylor(P,x,i) - mtaylor(mtaylor(P,x,i), t,j)):
end proc:
```

Explanation: These functions compute the polynomial remainder after factoring out $x^j y^i$ (or $t^j x^i$). The requirement that the remainder is zero gives the algebraic equations.

11. Defining the Unknown Coefficients

The homogeneous polynomials $R_{i,j}, S_{i,j}, \ldots$ are written as sums of monomials with unknown coefficients $cR_{\ldots}, cS_{\ldots}, \ldots$.

```
for j from 0 to m-0 do
    Rxy[m-0-j,j] := add(add(cR[m-0-j,j,dR-q-r,q,r]*1^(dR-q-r)*x^q*y^r, q=0..dR-
        r), r=0..dR):
od:

for j from 0 to m-3 do
    Sxy[m-3-j,j] := add(add(cS[m-3-j,j,dS-q-r,q,r]*1^(dS-q-r)*x^q*y^r, q=0..dS-
        r), r=0..dS):
od:

for j from 0 to m-6 do
    Uxy[m-6-j,j] := add(add(cU[m-6-j,j,dU-q-r,q,r]*1^(dU-q-r)*x^q*y^r, q=0..dU-
        r), r=0..dU):
od:

for j from 0 to m-9 do
    Vxy[m-9-j,j] := add(add(cV[m-9-j,j,dV-q-r,q,r]*1^(dV-q-r)*x^q*y^r, q=0..dV-
        r), r=0..dV):
od:

for j from 0 to m-12 do
    Wxy[m-12-j,j] := add(add(cW[m-12-j,j,dW-q-r,q,r]*1^(dW-q-r)*x^q*y^r, q=0..
        dW-r), r=0..dW):
od:
```

Explanation: Similar blocks are present for the t, x chart (with Rtx, etc.). These define the variables of the linear system.

12. Forming the Linear System and Reducing Modulo p

The equations from both charts are collected and reduced modulo $p = 5$.

```
xyEquations_Add := {}
for k from 0 to m/3 do
    for j from 0 to m-3*k do
        xyEquations_Add := xyEquations_Add union xyEquations[m-j-3*k,j,k]:
    od:
od:
Equations_xy := xyEquations_Add:

txEquations_Add := {};
for k from 0 to m/3 do
    for j from 0 to m-3*k do
        txEquations_Add := txEquations_Add union txEquations[m-j-3*k,j,k]:
    od:
od:
Equations_tx := txEquations_Add:

Equations := Equations_xy union Equations_tx mod p:
Nombre_Equations := nops(Equations);

Variables := {seq(seq(seq(cR[m-0-j,j,dR-q-r,q,r], q=0..dR-r), r=0..dR), j=0..m
    -0)}
    union {seq(seq(seq(cS[m-3-j,j,dS-q-r,q,r], q=0..dS-r), r=0..dS), j=0..m-3)}
    union {seq(seq(seq(cU[m-6-j,j,dU-q-r,q,r], q=0..dU-r), r=0..dU), j=0..m-6)}
    union {seq(seq(seq(cV[m-9-j,j,dV-q-r,q,r], q=0..dV-r), r=0..dV), j=0..m-9)}
    union {seq(seq(seq(cW[m-12-j,j,dW-q-r,q,r], q=0..dW-r), r=0..dW), j=0..m
        -12)}:

Nombre_Variables := nops(Variables);
```

Explanation: The equations are the coefficients of the Taylor expansions after the divisibility conditions have been applied. The number of equations and variables is printed for information.

13. Solving the System

The linear system over $\mathbb{F}_5$ is solved with `msolve`. The solution is printed; for the vanishing to hold, all coefficients must be zero.

```
Solutions := msolve(Equations,p):
Verification := seq(op(2,op(i,Solutions)),i=1..nops(Solutions)):
indets({Verification}):
nops(indets({Verification})):

assign(Solutions):
```

Explanation: `msolve` returns the unique solution; we assign it so that the coefficients are set to their values (which are zero in the vanishing case).

14. Output Verification

Finally, the code prints the resulting coefficients (they should all be zero). The loops that follow assign the computed values to the variables and then set the polynomials to zero, confirming the vanishing.

```
for j from 0 to m-0 do
    Voir_R[m-0-j,j]:= add(add(cR[m-0-j,j,dR-q-r,q,r]*T^((dR-q-r))*X^q*Y^r, q
        =0..dR-r), r=0..dR):
od:

for j from 0 to m-3 do
```

```
    Voir_S[m-3-j,j]:= add(add(cS[m-3-j,j,dS-q-r,q,r]*T^((dS-q-r))*X^q*Y^r, q
        =0..dS-r), r=0..dS):
od:

for j from 0 to m-6 do

```

Explanation: The last lines explicitly set the polynomials to zero, indicating that the only solution is the trivial one. This verifies the vanishing for the chosen Fermat conics modulo 5, and by semi-continuity the same holds for generic conics.

Conclusion

The Maple code implements the algebraic verification of the Key Vanishing Lemma II for the most challenging case $(m, t) = (13, 9)$. The computation, which involves tens of thousands of equations and variables, terminates with the only solution being zero, thereby proving the required vanishing result. The same procedure applied to all other required (m, t) pairs yields the full Key Vanishing Lemma II.
